TITLE: Experience of the Czechoslovak industry in protecting
equipment exported to countries with tropical climates.
(Opyt Chekhoslovatskoy promyshlennosti po zashchite
oborudovaniya, eksportiruyemogo v strany s
tropicheskim klimatom).

PERIODICAL: "Metallovedenie i Obrabotka Metallova" (Metallurgy and
Metal Treatment), 1957, No.6, pp.59-63 (U.S.S.R.)

ABSTRACT: The authors of this paper became acquainted with Czech
practice in a number of Czechoslovak works. In
Czechoslovakia the corrosion conditions are sub-
divided into the following four groups: very favourable
(closed dry spaces); favourable (spaces in which
atmospheric conditions act periodically); average
conditions and difficult corrosion conditions
(industrial atmosphere of seaside regions). Equipment
intended for tropical climates is treated as being
subjected to the most severe conditions of corrosion.
Czech practice is described as regards protective
painting, electro-plating (3-layer Cu-Ni-Cr plating,
cadmium plating followed by chromating, zinc plating
followed by chromating and in some cases by coating
with lacquer), copper-plating, nickel-plating,

663

(Cont.)

chromating, cadmium-zinc plating, anodising of aluminium and its alloys, conservation and packing. Fundamentally the materials and technology do not differ greatly from those used for goods supplied to countries with temperate climates. The main differences are: the enamel is made one to two layers thicker; in the case of varnishing electrical equipment and machine tools, coating enamels are used which contain fungicide additions; oil bases are used having a high content of minium; in the case of synthetic enamels, enamels with aluminium powder as pigments are used and extreme care is taken to produce a good surface quality prior to coating. Highly qualified personnel is used for the painting and surface treatment work. For tropical conditions coatings consisting of copper-nickel-chromium layers of a total layer thickness of about 30 to 45 μ are widely used; cadmium coating (8 to 15 μ) with subsequent chromating is used for springs; zinc coating (8 to 35 μ) with subsequent chromating is used predominantly for small fixing components which after fitting are varnished. Vaseline with various

663

(Cont.)

additions are used for conservation purposes. For protecting ferrous metals during storage and transportation a volatile inhibitor, dicyclohexo-aminonitride, is used.

Scientific Conference on the strength of elements of
turbo-machinery at elevated temperatures (Nauchnoye
sobranie po voprosam prochnosti elementov
turbo-mekhanicheskikh pri vysokikh temperaturakh).

Ukrainian Academy of Sciences, Otdeleniye Tekhnicheskikh
Nauk, No.2, pp. 165-167 (USSR).

A scientific conference was held in Kiev between
September 28 and October 2, 1957 on problems of strength
of elements of turbo-machinery at elevated temperatures
which was convened by the Institute of Metallurgical Materials
and Special Alloys (Institut Metallokeramiki i spetsialnykh alloy),
the Institute of Structural Mechanics
(Institut Strukturnoy Mekhaniki) and the Institute
of Thermal Power (Institut Teploenergetiki i Mekhaniki
Mazilmakov BSR) of the Ac.Sc. Ukrainskoy SSR.
People participated representing scientific and
establishments and works of Moscow, Leningrad,
Kiev, Minsk, Kuybyshev, etc. In his opinion
Corresponding Member of the Ac.Sc. Ukrainskoy SSR
pointed out the importance of the problem of the
natural strength of components of turbo-mach-

TITLE: Corrosion Cracking of Austenitic Steels at Elevated Temperatures and Pressures (Korrozionnoye rastreskivaniye austenitnykh staley pri povyshennykh temperaturakh i davleniyakh)

PERIODICAL: Metallovedeniye i Obrabotka Metallov, 1958, Nr 6, pp 25-32 (USSR)

ABSTRACT: The aim of the work described in this paper was to develop a method of corrosion tests under stress pertaining in steam superheaters and steam piping. The austenitic steels 1Kh18N12T, 1Kh18N9T and EI257 were investigated. The chemical analyses of these are given in Table 1, p.26 and the heat treatment regimes and mechanical properties in Table 2, p.26. In developing a method of investigation it was necessary to reproduce the effect of all the fundamental operational factors pertaining inside steam generation equipment. The experiments were carried out by the method of recording the curves of long duration corrosion strength using a UIM-5 test machine, a sketch of which is shown in Fig.1, p.27. Due to the high demands regarding the hermeticity of the specimens, it was necessary to use

Card 1/4

SOV-129-58-6-7/17

Corrosion Cracking of Austenitic Steels at Elevated Temperatures and Pressures

welded joints. A tubular specimen was used for combining the functions of the autoclave and the specimen (invention of the authors of this paper). During the manufacture of the specimen transverse scratches on the internal surface were eliminated by lapping by hand. The tensile stresses in the specimen were produced by the tensile forces of the machine and by means of internal pressure. The influence was investigated of mechanical stresses, of the composition and concentration of the solutions, and of the influence of heat treatment. The graph Fig.2 shows the results of long duration corrosion strength tests on the investigated boiler type austenitic steels. In Fig.4 the dependence is graphed of the time to failure of a specimen on the concentration of a solution of NaOH (stress; 30 kg/mm²). In Fig.5 the dependence is graphed of the time to failure of a specimen of the same steel on the concentration of NaCl in a 3% solution of NaOH. In Fig.6 the dependence is graphed of

Card 2/4

SOV-129-58-6-7/17

Corrosion Cracking of Austenitic Steels at Elevated Temperatures
and Pressures

the time to failure of a specimen on the test temperature. The tests carried out by means of the technique for testing the long duration corrosion strength of austenitic steels in aqueous solutions at elevated temperatures and pressures allow the following conclusions to be made: (1) The steels 1Kh18N12T, 1Kh18N9T and EI257 tend to corrosion cracking in alkali solutions (the character of the failure is predominantly transcrystalline); this tendency is greatest for the steel EI257 and weakest for the steel 1Kh18N12T. (2) Of all the investigated steels, the corrosion cracking in a pure distillate with access of oxygen at 100°C occurred only for the steel EI257 during the tests lasting 1000 hours. (3) The action of the pure distillate at 300°C for 500 hours with a limited access of oxygen did not cause corrosion cracking of the investigated steels. The solutions of NaCl, Na₃PO₄, Na₂HPO₄, Na₂SO₄, Na₂SO₃ in absence of oxygen or in presence of a limited access of oxygen, do not cause corrosion cracking of austenitic steels. (4) The concentration curve of long duration corrosion strength of austenitic steels in alkali media does show a limit. Thus, the critical concentra-

Card 3/4

SOV-129-58-6-7/17

Corrosion Cracking of Austenitic Steels at Elevated Temperatures
and Pressures

tion of alkali for the steel 1Kh18N9T at 210°C and
 $\sigma = 30 \text{ kg/mm}^2$ is 3% and at 330°C it approaches 1%.

(5) Addition of NaCl to alkali solutions showed an inhibiting effect on the processes of corrosion cracking.

(6) The relation between the time to failure and the absolute test temperature in corrosion cracking tests in alkaline media show an exponential character. (7) Even if the heat treatment does not show an appreciable influence on the corrosion strengths of the steels 1Kh18N9T and EI257 inside alkali media, it can prevent corrosion cracking since it results in the removal of internal stresses. There are 7 figures, 4 tables and 8 references, of which 6 are Soviet, 1 English and 1 German.

TITLE:

The Micro-Electro-Chemical Method for the Investigation of
the Corrosion of Metals Under Stress (Mikroelektrokhimicheskiy
metod issledovaniyu korrezii metalia pod napryazheniyem).

JOURNAL:

Zavodskaya Laboratoriya, 1950, Vol. 24, Nr 2, pp. 167-173 (USSR)

NOTES:

An apparatus was developed which makes possible microscopic investigations of metal samples during stress in a corrosive medium as well as the measuring of the electric potential. In principle this apparatus is composed of a device for various weights effecting the change of the stress (tension) of the sample; then the basin with the corrosion liquid in which the sample to be investigated is placed, the microscope and the electric measuring- and recording instrument. As corrosion liquids 0.01m HCl + 0.03% K₂C₂O₄ or 0.05m HCl + 0.2% H₂O₂ were used. Samples of cast iron with sphaero graphite, steel 3H-69 and cast iron 16-13-3T, as well as stabilized forging steel 3H 572 were investigated. The results obtained prove the theory of G. V. Arimov on the character of the potential

Card 1/5

The Micro-Electro-Chemical Method for the Investigation of
the Corrosion of Metals under Stress

change on structure surfaces; in a concrete case, for example, graphite and perlite have positive electrode potentials in relation to ferrite and in the system operate as cathodes. With the sample of cast iron 16-13-3T the assumption was proved that δ' ferrite forms the cathode in the microcorrosion element austenite- δ' ferrite. In order to obtain a comparison between samples under stress and those not under stress the potential differences between two samples, one under stress and one not under stress, were measured. For this purpose a special method was developed. From the graphical data obtained can be seen that there is a potential difference which increases with the increase of the stress applied, and that this increase is proportional to the current of the corrosion power. With the samples of steel 34M69 a special tendency for intercrystalline corrosion was observed. The potential difference between the grain bodies and the grain boundaries leads to dangerous corrosion phenomena-crack corrosion. The electro-chemical factors, according to the results obtained, play an important part in the phenomenon

TITLE: Cyclic strength of austenitic steels under conditions
of high temperature gas corrosion. (Tsiklicheskaya
prochnost' austenitnykh staley v usloviyah
vysokotemperaturnoy gazovoy korrozii).

PERIODICAL: Metallovedeniye i Obrabotka Metallov, 1958, No.3,
pp. 6-10 + 1 plate facing p.24. (USSR).

ABSTRACT: The authors considered it of interest to study the
influence of high temperature gas corrosion on the
fatigue strength of materials used for turbine blades.
The tests were effected on a test machine 98-M,
described in earlier work (Ref.1) which permits
determining the strength of a cantilever specimen in
the case of circular symmetrical bending with a
frequency of 2800 cycles per minute in air and in
various gaseous media at room temperature as well as at
elevated temperatures. The fatigue strength was studied
for the two austenitic steels 9Н612 and 3Н673 after
standard heat treatment consisting of hardening and
stabilisation annealing. The results of short duration
tensile tests at 20 and 650°C are entered in Table 1.

Card 1/3 The influence of various quantities of SO₂ admixtures

129-3-2/14

Cyclic strength of austenitic steels under conditions of high temperature gas corrosion.

on the fatigue strength is illustrated by the graphs, Figs.1-3. The simultaneous influence of water vapour and SO₂ on the fatigue strength is illustrated by the graphs, Figs. 5 and 6. The loss in weight of the specimens for the two corrosive media containing respectively 0.3% SO₂ + 6% H₂O and 0.3% SO₂ for the steel 3M 612 at 650°C is graphed in Fig.7. Fig.4 shows a micro-photo of a micro-crack in this steel after fatigue tests at 650°C in air containing admixtures of SO₂. It is concluded that at 650°C admixtures of SO₂ reduce the cyclic strength of austenitic steels; air containing 0.3% SO₂ will reduce the fatigue limit of the tested austenitic steel by 10 to 15% compared to the values obtained in pure air. Presence of SO₂ also increases the steepness of the fatigue curves which indicates an increase in the intensity of the drop of the fatigue limit. Increase of the SO₂ concentration in the air from 0.3 to 5% brings about a further gradual decrease of the fatigue limit. In presence of SO₂ cyclic stresses bring about a change over from uniform corrosion to localised corrosion which results in a reduction of the

Card 2/3

129-3-2/14

Cyclic strength of austenitic steels under conditions of high temperature gas corrosion.

fatigue strength. With increasing air humidity, the adverse effect of SO_2 on the fatigue strength weakens and in an atmosphere simulating the combustion products of fuel (0.3% SO_2 and 6% H_2O) practically no reduction of the fatigue limit is observed for tests covering 10^8 cycles.

There are 7 figures, 1 table and 2 Russian references.

PURPOSE: This book is intended for metallurgical engineers, research workers in metallurgy, and may also be of interest to students of advanced courses in metallurgy.

CONTENTS: This book, consisting of a number of papers, deals with the properties of heat-resistant metals and alloys. Each of the papers is devoted to the study of the factors which affect the properties and behavior of metals. The effects of various elements such as Cr, Mo, and Ni on the heat-resisting properties of various alloys are studied. Deformation and working properties of certain metals are related to the thermal conditions of hydrogen treatment, circulation of hydrogen, and diffusion of hydrogen through the metal. The properties of electrical insulators are examined. One paper describes the apparatus and methods used for growing monocrystals of metals. Boron-base metals are artificially eliminated and evaluated. Results are given of studies of literature bonds and the behavior of atoms in metal. Tests of turbine and compressor blades are described. No generalities are mentioned. References accompany most of the articles.

TITLE:

The Methodology of Continuous Corrosion Investigations in Liquid Media at Increased Temperatures and Pressures (Metodika dlitel'nykh ispytaniy na korroziyu v zhidkikh sredakh pri povyshennykh temperaturakh i davleniyakh)

PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 2,
pp 204 - 205 (USSR)

ABSTRACT:

An investigation was made of the tendency toward destructions of austenite boiler steel caused by corrosion in liquids in correspondence with the working conditions in steam super-heaters and steam pipes of the boilers SVP. This investigation was carried out in order to examine the resistance of these steels at simultaneous effects of increased pressure, high temperature, and mechanical stress in the corrosion medium. An appropriate testing method was developed (Ref 1). An apparatus of the UIM-5 type was used for recording the diagrams of the continuous corrosion resistance at increased pressure and temperature, since the apparatus normally used (Ref 2) as well as the attachments to the IP-2 apparatus

Card 1/2

The Methodology of Continuous Corrosion Investigations in Liquid Media at Increased Temperatures and Pressures SOV/32-25-2-37/78

(Ref) suggested by V. N. Gulyayev and A. V. Ratner are insufficient. The sample was welded into a tube with a corrosion liquid consisting of 3% NaOH + 0.15% NaCl (Fig 1) and tested at 330° and a pressure of approximately 130 atmospheres. Austenite steel EI 257, 1Kh18N12T, 1Kh18N9T and a ferrite-martensite steel EI 754 (with 11% Cr and slight Ni, V, Mo and Nb additions) were tested. The test results show that the steel 1Kh18N12T has the highest resistance, while the steel EI 257 exhibits the lowest resistance (Fig 2). It was found that the presence of a welding seam has no effect on the continuous corrosion resistance (Fig 3). There are 3 figures and 4 references, 3 of which are Soviet.

TITLE: Protection of Pearlitic Steels Against High Temperature
Gas Corrosion ✓

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
1960, No.11, pp.39-42 ✓

TEXT: The authors investigated chemical nickel plating of
the refractory steel 15XMFKP (15KhMFKR) of the following
composition: 0.15% C, 0.21% Si, 0.48% Mn, 1% Cr, 1.1% Mo, 1.4% Co,
0.3% V, 0.006% B, 0.02% S, 0.03% P. After washing in benzine,
degreasing with Vienna lime and etching in a 50% hydrochloric acid
solution, the specimens were subjected to chemical nickel plating
at 90 to 92°C in a solution containing 21 g/litre of nickel
chloride, 24 g/litre sodium hypophosphate, 10 g/litre sodium acetate,
pH = 4.8-5.3. The plating solution was renewed every hour. Chemical
analysis showed that the deposited layer contained 7.5 to 9% P. To
obtain a high bond strength between the coating and the steel and to
improve its mechanical properties, the specimens were heat
treated at 400°C for 1 hour. The coatings remained fully ✓

Card 1/3

S/129/60/000/011/009/016
E073/E535

Protection of Pearlitic Steels Against High Temperature Gas Corrosion
conserved without any traces of failure or cracking after 90°
bending of the specimen. Investigation of the corrosion stability
was carried out in air and super-heated steam at 650°C for 1000 hrs,
with intermediate removal of the specimens after 50, 100, 200 and
500 hours. The following conclusions are arrived at:

- 1) No structure was revealed in the coating layer prior to heat treatment.
- 2) After heat treatment a layering of the coating was observed, which is attributed to the periodic nature of the deposition of the coating.
- 3) After tests involving holding the specimens at 650°C in steam and in air, the structure of the layer consisted of a solid solution of P in nickel with inclusions of particles of the excess phase Ni₃P, which with increasing temperature or increasing holding time at the given temperature becomes less disperse.
- 4) After holding for 1000 hours at 650°C, the coatings maintained a relatively high hardness ($H_V = 728$) below the oxide film and, therefore, this type of plating is promising for components which are exposed to friction under normal and elevated temperatures.

TITLE: Wear-resistant chromium plating of cylindrical worm wheels and tests
of plated worm wheels in transmissions with cast iron gears

PERIODICAL: Vestnik mashinostroyeniya, no. 12, 1960, 21 - 26

TEXT: The article presents details of Engineer V. Ye. Khromov's plating
method for the work profile of worm shafts (Author's Certificate No. 127120), and
the results of tests of so plated worms in transmissions with cast iron worm gear
instead of usual bronze gear. The purpose of plating is economy of nonferrous
metal. Hard coating may also make superfluous the conventional quenching and case
hardening of worms. Single-thread and double-thread worms were made of "45" steel
with HB 160-217. The plating set (Fig. 1) has an anode in the form of a metal
coil (1) with two plastic discs (2). The detachable coil is held by two connection
plates and bolts. The worm is placed between its two symmetric halves, and current
is fed from anode rods to each half separately, from anode hooks (4 and 5). The
worm is connected to the cathode by hooks (6) made of copper or brass and plated
with tin.

Wear-resistant chromium plating of cylindrical...

with nickel. The module, profile angle, pitch diameter and thread lead angle of the anode coil are matching the worm. The anode coil groove width in normal cross section on the pitch cylinder (δ_{n1}) is determined by the equation:

$$\delta_{n1} = \frac{2r}{\cos d} + \delta_n$$

where d is the profile angle in normal cross section; δ_n - the thread thickness on the worm in normal cross section on pitch cylinder; r - the interelectrode space. The recommended and practically verified space between the anode and cathode is 30 - 35 mm, but it is not possible in this specific case and could be only few millimeters wide. The short space affects the plating process, and this was kept in view. The anode coils material was Cr.3 (St.3) steel. For plating large lots of worms it is better to use an alloy of 95% Pb, 3% Sb and 2% Sn. The worms were warmed for 2 - 5 min in the bath, then anode-pickled for 1 min, and plated in 800-1 bath. The electrolyte composition is 230 - 250 g/l CrO_3 , 1.8 - 2.7 g/l H_2SO_4 . The hardness of chromium deposit obtained with cathode current of 40 amp/dm² was 650 - 700 and 950 - 1,000 kg/cm². The hardness was measured on "witnesses" plated together with the worms, using a ПМТ-3 (PMT-3) tester with 100 g load on the

Card 2/4

indenter. The deposited chromium layers were from 0.1 to 0.14 mm deep. Tests revealed that the efficiency of worm gear transmissions varied with changing load, i.e., increased with increasing worm rpm. The highest efficiency reached was 68 - 70% at 280 - 300 kg/m load on the worm gear shaft; the contact shear stresses in teeth of single-thread worm transmission reached 800 kg/cm² at 5 m/sec sliding speed, which is much higher than is permissible for cast iron gears; the friction factor at highest efficiency was 0.04. Coating hardness 650 - 700 kg/mm² proved insufficient, it is recommended to use 950 - 1,000 kg/mm². The recommended coating thickness is 0.10 - 0.15 mm. The wear of the worm gear was uneven, with a maximum on the entrance portion of the teeth, therefore, it is concluded that the couple must work in before normal operation, but in general cast iron gears can be used. Tests were conducted by TsNIITMASH at Elektrostal'skiy zavod tyazhelogo mashinostroyeniya (Elektrostal' Heavy-Duty Machinery Plant), and Moskovskiy zavod elektrotermicheskogo oborudovaniya (Moscow Electric Heat Equipment Plant). Both plants have started using chromium-plated worms. D. V. Rozov and F. A. Orlov of the Elektrostal' Heavy-Duty Machinery Plant took part in tests. There are 5 figures and 7 Soviet-bloc references.

TITLE: Creep strength of the steel 1X14H14B 2M
(1Kh14M14V2M) operating in high pressure steam

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
no.7, 1962, 31-53 (+ 1 plate)

TEXT: The effect of high pressure steam on the creep strength of this steel (composition: 0.15% C; 0.54% Si; 0.59% Mn; 0.019% S; 0.024% P; 13.43% Cr; 13.85% Ni; 2.3% W; 0.44% Mo) in the austenised state was studied under conditions pertaining during normal operation in very high pressure steam superheaters.

The proneness to intercrystallite corrosion was determined by boiling standard specimens in a solution containing 70 ml H₂SO₄, 30 ml HNO₃, and 10 g CuSO₄ per litre. Superheated steam (580 °C, 185 atm) lowers somewhat the creep strength and the plasticity of the steel. Specimens tested in high pressure steam showed a greater number of cracks than those tested in air.

In both cases the cracks were intercrystalline.

TITLE: Long term corrosion resistance of Kh18N10T steel upon alternate wetting and drying

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 4, 1964, 18-21 and bottom half of insert facing p. 40

TOPIC TAGS: corrosion resistance, Kh18N10T steel, austenitic stainless steel, K-7 test apparatus, moisture corrosion resistance, tensile force, yield strength

ABSTRACT: The corrosion resistance of austenitic stainless steel upon prolonged exposure to alternate wetting and drying at temperatures to 350° and pressures to 100 atmospheres was tested in the K-7 apparatus (fig. 1). The curve for the corrosion resistance (as determined by visual examination) of Kh18N10T steel at various stresses was constructed. At 30-40 kg/mm² there is a great tendency toward corrosive cracking, with the corrosion depending little on the

α
tensile force. At 27.5-30 kg/mm² the effect of stress upon corro-
sion resistance is quite noticeable. At 25 kg/mm², a force somewhat
higher than the yield strength of the Kh18N10T steel, the sample
appeared resistant to corrosion during the 500 hour test. Orig.

TITLE: Nickel plating chromium nickel austenitic steel

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 4, 1964,
21-24, and insert facing p. 41

TOPIC TAGS: pearlitic steel, austenitic steel, chrome plating, thermodiffusing
plating, oxide film, electrochemical etching, adhesive strength, microhardness,
diffusion layer, metal wearability

ABSTRACT: Pearlitic steel is unsuitable for the production of steam turbine parts
working at 580-600C and more; heat resistant austenitic steel is also unsuitable
for that purpose because of its poor wearability. These considerations prompted
the development of a chemical method of nickel-plating high-alloy chrome nickel
austenitic steel (Kh18N9T and KhN35VT). But this type of steel is usually co-
vered with an oxide film which is not easily removable and which prevents the
adhesion of the coating to the ground coat. All the known chemical and electro-
chemical etching methods were used to remove the oxide films but none of them

Card 1/2

L-10529-65
ACCESSION NR: AP4030664 3

produced the desired results. Satisfactory results were finally achieved in the case of the mentioned steel samples by (i) washing them in gasoline; (ii) electrochemical degreasing in a standard alkaline solution at 70C for 5-7 min.; (iii) washing them in hot and cold water; (iv) cathode processing in a 20-25% solution of caustic soda at 70-30C for 5-6 minutes until an even thin brown layer appears and a number of other methods. A study of the increased hardness produced by the nickel plating process justifies its recommendation for the improvement of the wearability of austenitic steel. Our new nickel-plating process is now used at the Venukovskiy plant in the production of important parts for steam turbines which must be highly wear resistant and scratchproof. The chemical method of nickel plating austenitic steel will considerably extend the service life of numerous vital steam and gas-turbine parts. (Orig. art. has: 2 figures and 2 tables.)

TITLE: Effect of alloying on the stress corrosion of stainless steels in concentrated chloride solutions

47,55 14

SOURCE: Zashchita metallov, v. 1, no. 1, 1965, 48-54

TOPIC TAGS: austenitic steel, stainless steel, steel alloy, nickel steel, manganese steel, molybdenum steel, stress corrosion, solution property, magnesium compound, chloride, corrosion resistant steel, crack propagation

ABSTRACT:

Fifteen experimental austenitic stainless steels and alloys, containing 0.04—0.10% carbon, 0.39—0.70% silicon, 0.36—23.94% manganese, 19.34—20.50% chromium, 10.21—45.10% nickel, and 0.90—1.13% niobium, and Kh18N10T standard stainless steel were tested for susceptibility to stress corrosion. One steel also contained 0.40% boron, and two others contained about 2.5% molybdenum.

Card 1/3

L 64559-65

ACCESSION NR: AP5007626

2

Nickel was found to have the most beneficial effect on the resistance to stress corrosion. In tests under conditions of constant deformation (flat specimens 3 mm thick bent into a horseshoe shape) in boiling 42% solution of magnesium chloride only three alloys, all containing approximately 45% nickel, withstood 500 hr without damage. Steels and alloys with a lower nickel content suffered more or less severe damage. At a nickel content of 25-35% the first cracks appeared after 25-50 hr. However, the time period in which cracks reached a depth of 1.5-3.0 mm (complete failure) amounted to 275 hr at 35% nickel and to only 75 hr at 25% nickel. Kh18N10T steel failed in less than two hours.

27

The effect of manganese is definitely negative. In relatively mild aggressive media, such as a solution of magnesium, this effect becomes noticeable only at nickel contents below 40%. However, under more severe testing conditions, such as 25% sodium chloride +0.5% potassium bichromate solution at 200C and a pressure of 16 atm, even 5% manganese in an alloy containing 40% nickel reduced the time of failure from over 500 hr to 200 hr.

Card 2/3

L 64559-65
ACCESSION NR: AP5007626

4

Molybdenum also has a negative effect. Although it prolongs somewhat the time at which the first cracks appear, it accelerates crack propagation.

In tests under constant load in boiling 42% solution of magnesium chloride the 500 hr rupture life of all steels and alloys containing 20—45% nickel and 0.50—20% manganese was roughly the same, 53.7—55.0 kg/mm², compared to 14 kg/mm² for Kh18N10T steel and all steels with a nickel content of less than 25%. Orig. art. has: 3 tables, 3 graphs, 2 figures.

TITLE: An electromagnetic piston pump. Class 59, No. 169401

SOURCE: Byulleten' izobreteniij i tovarnykh znakov, no. 6, 1965, 111

TOPIC TAGS: piston pump, electromagnetic pump, pump pressure equalizer

ABSTRACT: This Author Certificate presents an electromagnetic piston pump with programmed measuring of forced corrosive liquids with the help of a timing relay (see Fig. 1 on the Enclosure). The relay is made with two chambers, one of which contains the electromagnetic windings and is filled with the cooling medium; the other chamber is the working cylinder. The piston rod of the working chamber is rigidly connected to the core of the electric magnet. To provide measured forcing of the corrosive liquids under various pressures, the electromagnetic windings are shielded by a thin-walled shield. This shield is relieved from the pressure by a bellows-membrane pressure equalizer established in the trunk line between the forced medium and the cooling medium. Orig. art. has: 1 figure.

TITLE: Apparatus for testing steel for corrosive cracking in aqueous solutions
with known concentration of salts and oxygen

SOURCE: Zavodskaya laboratoriya, v. 31, no. 4, 1965, 501-503

TOPIC TAGS: steel, steel corrosion, corrosive cracking, oxygen / Kh18N10T steel,
EP17 steel, EI695R steel, EP184 steel

ABSTRACT: An apparatus for high-temperature testing of steels for their tendencies to corrosive cracking in aqueous solutions with known concentrations of salts and oxygen was developed (see Fig. 1 on the Enclosure). It consists of an autoclave 1 with the specimens, a convection loop 2 with a heater 3 and a cooler 4, a pressure stabilizer 5, a pump 6, a doser 7, a tester 8, and an intermediate tank 9. Experiments are conducted on crescent-shaped specimens. The necessary oxygen concentration is achieved by using compressed gas. At 350°C a pressure of 200 atm is maintained in the system. The interchange of liquid between the autoclave and the pressure regulator is caused by periodic temperature oscillations during the process of regulation. The salt content is

Card 1/3

L 49445-65

ACCESSION NR: AP5009921

2

corrected with the doser which is also used for a more intensive liquid exchange. The intermediate tank serves for adding gas to the stabilizer in the course of an experiment. Austenite steels Kh18N10T, EP17, EI695R, and EP184 were tested in a solution containing 500 g/liter of chloride ions and 0.4 mg/liter of oxygen. It was found that under these conditions cracking may occur very rapidly (in 500 hr). Steels EI695R and EP184 proved to be most resistant. An addition of nickel in steel increased its resistance. This method may be applied to testing for general, contact, and intercrystalline corrosion in water with a known oxygen content. Orig. art. has: 1 diagram.

TITLE: On the nature of the stress corrosion cracking of austenitic steels and basic factors affecting this process

SOURCE: Zashchita metallov, v. 2, no. 3, 1966, 257-278

TOPIC TAGS: stress corrosion, austenitic steel

ABSTRACT: The article analyzes literature data on the nature and mechanism of the process of stress corrosion cracking of austenitic steels in chloride solutions and discusses the principal factors affecting the generation and development of fractures under stress corrosion conditions. It is shown that thus far no theory has been developed to provide an accurate explanation for the stress corrosion process, but that one should be advanced in the near future. All the known factors determining the tendency of austenitic steel toward stress corrosion cracking are divided into two main groups: (a) external factors related to the conditions of the medium surrounding the metal, and (b) internal factors determining the physicochemical properties of the metal itself (i.e., chemical composition, structure, degree of deformation, etc.). The manner in which two major factors, the composition and temperature

TITLE:	<u>Copper plating of steel components in polyethylene-polyamine electrolytes</u>		
SOURCE:	Byulleten' tekhniko-ekonomiceskoy informatsii, no. 8, 1966, 3-5		
TOPIC TAGS:	copper plating, electrolyte, polyamine compound, ammonium sulfate		
ABSTRACT: The authors discuss the use of new electrolytes developed at the <u>Central Scientific Research Institute of Technology</u> and <u>Machine Building</u> for copper plating. These solutions are based on polyethylene-polyamine copper complexes which are superior in many respects to cyanide electrolytes. The optimum polyethylene-polyamine copper-plating electrolyte has the following composition (g/l) copper sulfate 45-55; polyethylene-polyamine 50-70; ammonium sulfate 100-150. The optimum solution has an alkalinity of pH 8.2-9.0, a temperature of 18-23°C an optimum current density of 0.6-1.0 a/dm ² . The current efficiency is 85-98% depending on current density and component concentration. Current efficiency decreases with an increase in current density, polyethylene-polyamine concentration past 75 g/l and ammonium sulfate concentration past 150 g/l. For copper plating complex parts with deep slots, grooves, blind holes; etc. the concentration of polyethylene-polyamine and ammonium sulfate should be in-

O
creased to 100-125 and 200 g/l respectively to increase the throwing power by a factor of approximately 1½ although the deposition rate is somewhat reduced in comparison with the optimum composition. Deposition rate under optimum conditions is 6-10 μ /hr. Plating procedure and sequence of operations are discussed.

Hardening and protecting parts against corrosion by the nickel plating method
(Uprocheniye i zashchita ot korrozii detaley metodom khimicheskogo nikelirovaniya)
Moscow, Izd-vo "Mashinostroyeniye", 65. 0127 p. illus., biblio. 4,000 copies
printed.

TOPIC TAGS: anticorrosion agent, heat resistant material, nickel plating, surface
hardening, austenitic steel, carbon steel, pearlitic steel, steam turbine

PURPOSE AND COVERAGE: This book describes the surface hardening and protection of
parts from corrosion in power equipment and other types of equipment by nickel plating.
Also shown is the techniques of applying nickel-phosphorus coatings to heat resistant
pearlitic and fire-resistant austenitic steel. The book discusses structural stabi-
lity, protection and hardening properties of the surface under high temperatures. Re-
sults are given from tests made of parts with nickel-phosphorus surfaces as well as an
experiment for industries use of this nickel plating method. The book is recommended
for workers in industrial laboratories, technicians and assistants in the field of anti-
corrosion technology and surface hardening of machine parts.

TITLE: A device for corrosion tests under stress at high temperature and pressure

SOURCE: Zavodskaya laboratoriya, v. 31, no. 10, 1965, 1265-1268

TOPIC TAGS: stress corrosion, high temperature effect, pressure effect

ABSTRACT: The article is a description of a device patented by the authors for studying corrosion in metals under stress at high temperatures and pressures (Author's Certificate No. 154078, published in *Byulleten' izobreteniy* No. 8 1963). Schematic diagrams are given of the instrument as a whole and of its principal parts. A general schematic of the device is shown in fig. 1 of the Enclosure. The unit consists of working chamber 1 with loading device 2, supercharger 3, intermediate storage vessels 4 and 5 and sampler 6. These elements form a closed circulation system with connecting tubes 7. The installation also contains a supply tank 8, a pressure-equalizing device 9, protection 10 and control 11 instrumentation located on a separate control board and in the cabinet of the device. The operation of the

TITLE: Siliconizing refractory metals in a glow discharge

SOURCE: AN UkrSSR. Institut problem materialovedeniya. Diffuzionnyye pokrytiya na
metallakh (Diffusion coatings on metals). Kiev, Naukova dumka, 1965, 38-44

TOPIC TAGS: refractory metal, metal siliconizing, glow discharge siliconizing,
molybdenum siliconizing, tungsten siliconizing, niobium siliconizing, tantalum sili-
conizing

ABSTRACT: Molybdenum, tungsten, niobium, and tantalum have been siliconized at 1000 to
1200°C by glow discharge in a mixture of silicon tetrachloride vapor and hydrogen
flowing at a pressure of 40 mm Hg and a rate of 0.5 l/min. The glow discharge starts
at 500—700 v. The rate of siliconizing in a glow discharge depended on the pressure
in the reaction chamber, the volume ratio and the rate of consumption of the silicon
tetrachloride and hydrogen, and the reaction temperature and was significantly higher
than that of conventional siliconizing in a gaseous medium. Molybdenum had a sili-
conized layer 25 μ thick in 5 min, and a layer 67 μ thick in 40 min. Higher rates
were also observed in tungsten, niobium, and tantalum. The siliconized coatings con-
sisted basically of disilicides of the respective metals. Tungsten siliconized at

ACC NR: AT5024870

1000C for 30 min had a one-layer coating consisting of WSi_2 with a hardness of 1865 dan/mm². Niobium and tantalum had two-layer coatings, the outer layers consisting of $NbSi_2$ and $TaSi_2$, respectively, and the inner layer having a lower silicon content. The inner layer of niobium had a hardness of 1125 dan/mm². Molybdenum siliconized at 1000C for 40 min had a three-layer coating; the hardness of the outer and innermost layers was 1565 and 1350 dan/mm², respectively. Molybdenum and tungsten disilicides had a tetragonal crystal lattice; niobium and tantalum had a hexagonal lattice. Siliconizing in a glow discharge can be done below the recrystallization temperature, which keeps the parts in the strengthened condition. The high efficiency of the process can be explained by the presence of an ionized medium and by the activated condition of the metal surface being siliconized. Orig. art. has: 4 figures. [MS]
